Cf. <https://reprog.wordpress.com/2010/04/19/are-you-one-of-the-10-percent/>

Am I one of the 10% of programmers who can write a binary search?

Blind attempt at doing it in ladder logic on a Programmable Logic Controller (PLC)

- The PLC program is written in ladder logic, which is a digital form, and extension, of relay logic
- PLCs are roughly analogous to GAWK reading from a never-ending input stream.
- Each pass, analogous to processing one GAWK input line, is called a scan

The sorted array has seven elements: 1; 2; 2; 3; 5; 6; 6; 6; the lengths tested run be from 0 to 8.

The range of sought values will be from 0 to 7.

This is the main program; on each PLC scan, this program will

- Select one problem from the set of 72 possibilities (eight lengths and seven sought values),
- Call the linear and binary searches
- Compare the results

END

Perform a linear search of a sought value in a sorted array of values

Inputs

- Sought value, T (0-7)
- Length of array (0-8)
- The sorted array, containing eight values: 1; 2; 2; 3; 5; 6; 6; 6.

Perform a linear search of a sought value in an array of values

Inputs

- Sought value, T (0-7)
- Length of array (0-8)
- A sorted array, containing up to eight values: 1; 2; 2; 3; 5; 6; 6; 6.

If the length of the array is less than 1, then the result is -98; don't perform a search

Loop over elements in array while the following conditions remains true:

- High index (offset from first element of array) is less than length of array, i.e. high index points to a value in the array,

AND

- Value at high index is less than or equal to sought value

On each pass through loop,

- MOVE value of high index to low index, and

- Increment high index

0000

Loop while the following condition remains true:
 - High index value is at least two greater than low index value

Maintain the following invariants:

- Array value at low index is less than or equal to sought value

AND

- EITHER high index is array length OR array value at high index is greater than or equal to sought value

N.B. Those invariants, if initially true, will eventually assign the low index to the offset of the last value in the array that is less than or equal to the sought value

N.B. Those invariants will be violated when the sought value is less than value of the first element in the array, however
 in that case at the end the low and high index values will be 0 and 1, respectively.

On each pass through loop,

- Calculate mid index value

- Shift either low or high index to mid index value to maintain the invariants above
